(54) Title: METHODS AND COMPOSITIONS FOR THE SELECTIVE INHIBITION OF GENE EXPRESSION

(57) Abstract

Disclosed are methods and compositions for the selective inhibition gene expression through the application of antisense RNA technology. Antisense RNA constructs of the present invention employ the use of antisense intron DNA corresponding to distinct intron regions of the gene whose expression is targeted for down-regulation. In an exemplary embodiment, a human lung cancer cell line (NCI-H460a) with a homozygous spontaneous K-ras mutation was transfected with a recombinant plasmid that synthesizes a genomic segment of K-ras in antisense orientation. Translation of the mutated K-ras mRNA was specifically inhibited, whereas expression of H-ras and N-ras was unchanged. A three-fold growth inhibition occurred in H460a cells when expression of the mutated ras p21 protein was down-regulated by antisense RNA and cells remained viable. The growth of H460a tumors in nu/nu mice was substantially reduced by expressed K-ras antisense RNA.

**METHODS AND COMPOSITIONS FOR THE SELECTIVE
INHIBITION OF GENE EXPRESSION**

5 The present invention relates to methods and nucleic
acid compositions for selectively inhibiting gene
expressing, involving the preparation and use of anti-
sense RNA molecules that encode sequences complementary
to distinct intron regions for the inhibition of, for
10 example, oncogene expression.

 It is now well established that a variety of
diseases, ranging from certain cancers to various genetic
defects, are caused, at least in part, by genetic
15 abnormalities that result in either the over expression
of one or more genes, or the expression of an abnormal or
mutant gene or genes. For example, many forms of cancer
in man are now known to be the result of, at least
indirectly, the expression of "oncogenes". Oncogenes are
20 genetically altered genes whose altered expression
product somehow disrupts normal cellular function or
control (Spandidos, et al., 1989).

 Most oncogenes studied to date have been found to be
25 "activated" as the result of a mutation, often a point
mutation, in the coding region of a normal cellular gene
or of a "protooncogene", that results in amino acid
substitutions in the protein expression product. This
altered expression product, in turn, exhibits an abnormal
30 biological function that somehow takes part in the
neoplastic process (Travali, et al., 1990). The
underlying mutations can arise by various means, such as
by chemical mutagenesis or ionizing radiation.

35 A number of oncogenes have now been identified and
characterized to varying degrees, including *ras*, *myc*,

-2-

neu, *raf*, *erb*, *src*, *fms*, *jun*, and *abl* (Travali, et al., 1990; Minna, 1989; Bishop, 1987). It is quite likely that as our knowledge of tumorigenesis increases, additional oncogenes will be identified and

5 characterized. Many of the foregoing, including *ras*, *myc* and *erbB*, comprise families of genes, whose expression product bear sequence similarities to other members of the family (Shih, et al., 1984; Bos, 1989; Schwab, et al., 1985). In the case of many of these gene families,
10 it is typical that oncogenesis involves an activation of only one member of the family, with other "unactivated" members serving a role in normal cellular functions (Id.).

15 The study of DNA-mediated gene transfer has revealed the existence of activated cellular oncogenes in a variety of human tumors (for review, see Cooper, et al., 1982). Oncogenes have been identified in human bladder, colon, lung and mammary carcinoma cell lines (Krontiris,
20 et al., 1981; Murray, et al., 1981; Perucho, et al., 1981), promyelocytic leukemia (Murray, et al., 1981), neuroblastoma (Shimizu, et al., 1983) and sarcoma cell lines (Pulciani, et al., 1982), and various solid tumors including carcinomas of the lung, and pancreas (Pulciani,
25 et al., 1982). Studies have demonstrated that various transforming genes detected by transfection correspond to activated cellular homologues of retroviral oncogenes (Pulciani, et al., 1982; Der, et al., 1982; Parada, et al., 1982; Santos, et al., 1982), although others have no
30 known retroviral cognate (Pulciani, et al., 1982; Lane, et al., 1982).

The *ras* oncogene family has been perhaps the best characterized to date (Barbacid, 1987; Bos, 1989). Most
35 of the identified transforming genes in human carcinomas have been a member of the *ras* gene family, which encode

-3-

immunologically related proteins having a molecular weight of 21,000 (p21) (Ellis, et al., 1981; Papageorge, et al., 1982). This family is comprised of at least 3 members, one transduces as H-ras in the Harvey strain of murine sarcoma virus (Ellis, et al., 1981), one as K-ras and Kirsten murine sarcoma virus (Ellis, et al., 1981), and one identified by low stringency hybridization to H-ras, termed N-ras (Shimizu, et al., 1983). As noted, all members of the ras gene family encode closely related proteins of approximately 21,000 Daltons which have been designated p21s (Ellis, et al., 1981). The level of p21 expression is similar in many different human tumor cells, independent of whether the cell contains an activated ras gene detectable by transfection.

Nucleotide sequence analysis of the H-ras transforming gene of the EJ human bladder carcinoma has indicated that the transforming activity of this gene is a consequence of a point mutation altering amino acid 12 of p21 from glycine to valine (Tabin, et al., 1982). Studies of proteins encoded by K-ras genes activated in four human lung and colon carcinoma cell lines indicated that the transforming activity of K-ras in these human tumors was also a consequence of structural mutations (Der and Cooper, 1983). Other mutations have been found to result in ras gene activation as well. For example, the H-ras gene activated in a lung carcinoma cell line encodes the normal amino acid position 12 but is mutated at codon 61 to encode leucine rather than glutamine (Yuasa, et al., 1983). An N-ras gene activated in a human neural blastoma cell line is also mutated at codon 61 but encodes lysine rather than glutamine (Taparowski, et al., 1983). Thus, studies such as these have indicated that ras genes in human neoplasms are commonly activated by structural mutations, often point mutations, that thus far occur at codon 12 or 61 with different

-4-

amino acid substitutions resulting in *ras* gene activation in different tumors.

Antisense RNA technology has been developed as an approach to inhibiting gene expression, particularly oncogene expression. An "antisense" RNA molecule is one which contains the complement of, and can therefore hybridize with, protein-encoding RNAs of the cell. It is believed that the hybridization of antisense RNA to its cellular RNA complement can prevent expression of the cellular RNA, perhaps by limiting its translatability. While various studies have involved the processing of RNA or direct introduction of antisense RNA oligonucleotides to cells for the inhibition of gene expression (Brown, et al., 1989; Wickstrom, et al., 1988; Smith, et al., 1986; Buvoli, et al., 1987), the more common means of cellular introduction of antisense RNAs has been through the construction of recombinant vectors which will express antisense RNA once the vector is introduced into the cell.

A principle application of antisense RNA technology has been in connection with attempts to affect the expression of specific genes. For example, Delauney, et al. have reported the use antisense transcripts to inhibit gene expression in transgenic plants (Delauney, et al., 1988). These authors report the down-regulation of chloramphenicol acetyl transferase activity in tobacco plants transformed with CAT sequences through the application of antisense technology.

Antisense technology has also been applied in attempts to inhibit the expression of various oncogenes. For example, Kasid, et al., 1989, report the preparation of recombinant vector construct employing *Craf-1* cDNA fragments in an antisense orientation, brought under the

-5-

control of an adenovirus 2 late promoter. These authors report that the introduction of this recombinant construct into a human squamous carcinoma resulted in a greatly reduced tumorigenic potential relative to cells transfected with control sense transfectants. Similarly, Prochownik, et al., 1988, have reported the use of Cmyc antisense constructs to accelerate differentiation and inhibit G₁ progression in Friend Murine Erythroleukemia cells. In contrast, Khokha, et al., 1989, discloses the use of antisense RNAs to confer oncogenicity on 3T3 cells, through the use of antisense RNA to reduce murine tissue inhibitor or metalloproteinases levels.

Unfortunately, the use of current antisense technology often results in failure, particularly where one seeks to selectively inhibit a member of a gene family. This is presumably due to the similarity in underlying DNA sequence, which results in the cross-hybridization of antisense RNA, which retards the expression of genes required for normal cellular functions. An example is presented by Debus, et al., 1990, who reported that in the case of ras oncogenes, antisense ras oligonucleotides kill both normal and cancer cells, which, of course, is not a desired effect.

Therefore, while it is clear that antisense technology shows potential promise as a means of external control of gene expression, it is equally clear that it does suffer particular draw backs, such as in its lack of selectivity where gene families are concerned. There is a particular need, therefore, for a general approach to the design of antisense RNA which will allow selective inhibition of gene expression, even in the case of closely related genes.

-6-

The present invention, in a general and overall sense, addresses one or more of the foregoing or other shortcomings in the prior art by providing a novel approach to the design of antisense RNA molecules, and their coding sequences, in a manner which allows their use to inhibit the expression of specific genes. The inventors believe that the approach offered by the present invention offers more specificity and selectivity than previous approaches. Additionally, it is proposed that the present invention will allow that the development of antisense technology having a much improved ability to inhibit specific gene expression, particularly in those instances where one desires to selectively inhibit a particular gene over that of closely related genes or other members of a gene family.

A principle feature of the present invention is the antisense RNA molecules themselves, which include a region that is complementary to and is capable of hybridizing with an intron region of the gene whose expression is to be inhibited. The inclusion of intron-complementary regions in the antisense RNA constructs of the present invention is believed to be the key to both an improved inhibitory capability as well as selectivity. By way of theory, it is proposed that the use of antisense intron regions provides an improved capability for at least two reasons. It is known that the structure of intron RNA plays a role in RNA processing.

The inventors propose that antisense introns bind to "sense" intron regions found on the initial RNA transcript of the gene, and affects proper RNA processing. Thus, subsequent translation of protein-coding RNAs into their corresponding proteins is retarded or prevented. The use of antisense introns are believed to provide selectivity of inhibition because the exon or "amino acid

-7-

encoding" region of RNAs coding for closely related proteins are often themselves closely related. This may not be the case for the introns of closely related genes. Thus, where intron regions between two genes are

5 distinct, antisense introns can be designed which will hybridize selectively to a selected gene family member, and not to other family members, and thereby inhibit selectivity.

10 As used herein, the term "intron" is intended to refer to gene regions that are transcribed into RNA molecules, but processed out of the RNA before the RNA is translated into a protein. In contrast, "exon" regions of genes are those regions which are transcribed into RNA

15 and subsequently translated into proteins.

Thus, where one seeks to selectively inhibit a particular gene or genes over a related gene or genes, the inventors propose the preparation and use of

20 antisense RNA molecules which encode an intron region or regions of the gene which one desires to inhibit selectively, that is distinct from intron regions of genes which one desires to leave unaffected. A "distinct" intron region, as used herein, is intended to

25 refer to an intron region that is sufficiently different from an intron region of another gene such that no cross hybridization would occur under physiologic conditions. Typically, where one intron exhibits a sequence homology of no more than 20% with respect to a second intron, one

30 would not expect hybridization to occur between antisense and sense introns under physiologic conditions.

While it is generally preferred that antisense introns be prepared to be complementary to an entire

35 intron of the gene to be inhibited, it is believed that shorter regions of complementarity can be employed, so

-8-

long as the antisense construct can be shown *in vitro* to inhibit expression of the targeted expression product. The inventors believe that the most important intron regions in terms of the preparation of antisense introns will be those regions closest to intron/exon junctions. This is the region where RNA processing takes place. Thus, it is proposed that one will desire to include it in the antisense intron sufficient complementarity with regions within 50-100 nucleotides of the intron/exon junction.

The inventors have found that some antisense exon sequences of the targeted gene can also be included in the antisense constructs of the present invention, so long as the resultant construct maintains its selectivity, and will not seriously inhibit genes whose continued function is relied upon by the cell for normal cellular activities. The amount of antisense exon sequence included within the antisense construct which can be tolerated will likely vary, depending on the particular application envisioned. For example, antisense constructs for down-regulation of K-ras expression have been prepared which include sequences complementary to exons II and III and all of intron II of the K-ras gene. These constructs contain antisense sequences to intron II of K-ras, and selectively inhibit K-ras expression relative to H-ras or N-ras. Thus, in this instance, the inclusion of sequences complementary to exons II and III of K-ras apparently did not result in the significant inhibition of the H-ras or N-ras genes, even though a 300 nucleotide region of complementarity existed with exons of the unaffected genes.

One can readily test whether too much antisense exon DNA has been included in antisense intron constructs of the present invention by simply testing the constructs in

vitro to determine whether normal cellular function is affected or whether the expression of related genes having complementary sequences are affected.

5 It is proposed that the antisense constructs of the present invention, whether they be the antisense RNA molecules (i.e., oligonucleotides) or nucleic acid molecules which encode for antisense RNA molecules, will have their principal application in connection with the
10 down-regulation of oncogene expression. The most preferred oncogenes for application of the present invention will be those which exist as a family of genes, where one desires to selectively inhibit one member of a
15 family over other members. In this regard, one may mention by way of example, the *ras*, *myc*, *erb* or *jun* families of oncogenes. Certain of these, such as the *ras* family, involves the activation of protooncogenes by a point mutation, which apparently results in the expression of a biologically abnormal product.

20 The present invention contemplates that antisense intron RNA can either be applied directly to cells, in the form of oligonucleotides incorporating antisense
25 intron sequences, or by introducing into the cell nucleic acid sequences that will encode the desired antisense construct. In the former case, it has been shown by others that antisense oligonucleotides can successfully traverse cellular membranes. The present inventors envision that such an approach may be an option to
30 therapy, particularly where the antisense oligonucleotides are successfully packaged to maintain their stability in circulation, for example, by liposome encapsulation.

35 Other techniques for direct insertion in the cells include, by way of example, electroporation, or calcium

-10-

phosphate transfection. Furthermore, where one desires to treat conditions of the bone marrow, bone marrow cells can be successfully removed from the body, treated with antisense constructs, and replaced into the body similar to the adoptive immunotherapy approach employed in IL-2 treatment.

It is proposed that a more preferred approach will involve the preparation of vectors which incorporate nucleic acid sequences capable of encoding the desired antisense intron construct, once introduced into the cells to be treated, preferably, these sequences are stably integrated into the genome of the cell. One example of such of vector construct would be a replication defective retrovirus, such as LNSX, LN or N2A, that is made infective by appropriate packaging, such as by GPtenvAM-12 cells. Although the retrovirus would inhibit the growth of the tumor, the expression of the antisense construct in non-tumor cells would be essentially harmless where one prepares a retrovirus construct which encode distinct antisense intron RNA in accordance with the present invention. In addition to retroviruses, it is contemplated that other vectors can be employed, including adenovirus, adeno-associated virus, or vaccinnia viruses (Hermonat, et al., 1984; Karlsson, et al., 1985; Mason, et al., 1990).

Therefore, in certain aspects, the present invention contemplates the preparation of nucleic acid molecules which comprise a coding region capable of expressing an antisense "intron" RNA molecule having regions complementary to and capable of hybridizing with an intron region of selected gene. Generally speaking, preferred nucleic acid molecules will be DNA sequences arranged in a vector, such as a virus or plasmid, and positioned under the control of an appropriate promoter.

-11-

However, antisense RNA can be itself an RNA molecule, such as retrovirus RNA into which the appropriate coding sequences have been incorporated. In either case, the nucleic acid encoding sequences will be arranged in a vector that will preferably be capable of stably integrating the antisense coding sequences into the genome of the targeted cell.

The particular promoter that is employed to control the expression of the antisense RNA in a vector construct is not believed to be particularly crucial, so long as it is capable of expressing the antisense intron RNA in the targeted cell of a rate greater than 5 fold that of the gene to be inhibited. Thus, where a human cell is targeted, it will be preferred to position the antisense RNA coding region adjacent to and under the control of a promoter that is capable of being expressed in a human cell. Generally speaking, such a promoter might include either a human cellular or viral promoter. By way of example, one may mention the RSV, N2A, LN, LNSX, LNSN, SV40, LNCX or β -actin promoter (Miller, et al., 1989; Hamtzoponlos, et al., 1989).

The most preferred promoters will be those that are capable of being expressed in a wide variety of histologic cell types, and which is capable of continuously expressing the antisense RNA. A preferred example is the β -actin promoter, because the promoter functions effectively in human epithelial cells. Other examples of promoters having a similar capability include RSV and SV40.

In further aspects, the present invention concerns a method of selectively inhibiting the expression of a gene product of a selected gene in a cell, which includes preparing an antisense RNA molecule having a region that

-12-

is complementary to and capable of hybridizing with a distinct intron region of the selected gene, followed by introducing the antisense RNA into the cell in an amount effective to inhibit the expression of the gene product.

5

In still further embodiments, the invention concerns a method for the inhibition of tumorigenicity of ras-transformed cells, which includes a first step of testing the cell to identify the particular ras gene that has
10 been activated, preparing an antisense RNA molecule which includes a distinct intron of the activated ras oncogene that is not found in an intron of ras genes which are not activated in the cell, and introducing the antisense RNA into the cell in amounts effective to selectively inhibit
15 the activated ras gene. The inventors have found that the invention has particular applicability to control of ras gene expression, particularly K-ras, and have shown that the expression of a particular ras gene can be effectively inhibited, without affecting cell viability.

20

In still further embodiments, the present invention relates to methods of preparing genetic constructs for the expressing of antisense intron DNA, which includes incorporation of genomic DNA fragments, as opposed to
25 cDNA, into appropriate vectors for subsequent intracellular incorporation. Of course, the use of cDNAs alone in the preparation of antisense RNA will not be in accordance with the present invention, in that, by definition, cDNAs will not include the required intron
30 sequences. However, intron sequences will be represented in genomic DNA, which therefore provides a useful source of DNA fragments for application to the present invention.

35

Fig. 1 A) The second exon of the K-ras gene was amplified from genomic DNA of H522, H322, Calu 1, H226,

-13-

H460a and human placenta by polymerase chain reaction (PCR), blotted onto a gene screen membrane and hybridized with ^{32}P end-labeled oligonucleotide probes. Fig. A1 shows the presence of wild-type glutamine residue (CAA) at 61 codon in five cell lines except H460a. The same blot was reprobbed with a histidine-specific mutated oligo probe (CAT) and only the H460a cell line PCR DNA hybridized (Fig. A2). The mutation was confirmed by direct PCR DNA sequencing. Wild-type K-ras 61 codon sequence in human placenta (Fig. A3) was compared with the H460a cell line (Fig. A4).

B) A 2 kb genomic DNA segment from the K-ras oncogene was subcloned into in Apr-1-neo vector in both a sense and antisense orientation. A 2 kb Eco RI/Pst I fragment containing second and third exon sequences together with adjoining flanking intron sequences was isolated from the SP6 vector (Oncogene Sciences) and Klenow enzyme was used to make blunt ends. Apr-1-neo vector was digested with Bam HI and blunt end ligation was performed to obtain the Apr-1-neo AS or Apr-1-neo A constructs.

C) A southern blot analysis of the K-ras oncogene in H460a and H460a transfectants. Blots were probed with P32 nick translated 2 kb Eco RI/Pst I insert DNA. 1) H460a, (2,3) H460a transfected with Apr-1-neo S C₁#1 and C₂#1 (4,5) H460a cells transfected with Apr-1-neo AS, C₃#32 and C₂#32, respectively.

D) A northern blot analysis of sense and antisense K-ras RNA. 1) H460a, (2,3) Apr-1-neo S transfectants, (4,5) Apr-1-neo AS transfected clones.

E,F) A Western blot analysis of K-ras specific p21-protein (1E) and total ras protein (1F) was performed

-14-

using either pan ras or K-ras specific monoclonal antibodies. 1) Calu-1 control cell line over expressing K-ras specific protein. 2) H460a; 3) H460a Apr-1-neo S; 4,5) H460a Apr-1-neo AS.

5

G) Map of plasmid pH β Apr-1-neo

Fig. 2 A) Schematic diagram of K-ras RNA synthesis. A segment of ras cDNA was amplified using oligonucleotide primers corresponding to the 5' region of first exon and 3' of second exon (indicated by arrows) for RNA PCR analysis.

B) An RNA PCR analysis was done to compare the level of K-ras message in H460a and H460a transfectants. As a control, a portion of p53 gene was co-amplified with p53 specific primer which served as an internal control.

C,D) H-ras and N-ras specific amplimers were used to quantitate H-ras/N-ras RNA in the transfectants and parental cell lines. p53 gene amplification is shown as an internal control.

Fig. 3 (A) In vitro growth curve. Cells were seeded at 10^4 cells/plate and grown for a seven day period. Cells were harvested and counted in a hemocytometer at 24 h intervals. Growth curves for H460A and H460A cells transfected with Apr-1-neo S vector do not show any significant difference, but H460A transfectants carrying Apr-1-neo-AS showed growth inhibition (Fig. B). Female BALB/C nu/nu mice were injected with 10^6 H460a cells subcutaneously in the left flank. Cross-sectional diameters of the external tumor were measured without knowledge of the cell group. Tumor volume was calculated by assuming a spherical shape with the average tumor diameter calculated as the square root

-15-

of the product of cross-sectional diameters. Palpable tumors were first detected on day 15. Each point represents the mean \pm SE. C3#32-AS (n = 5), C3#1-S (n = 5), H460a (n = 3). C3#32-AS was compared to C3#1-S or H460a on days 20, 25, 30, 35 (p < .05 by Wilcoxon's Test).

The present invention relates generally to techniques for down-regulating the expression of selected genes, particularly those which contribute to the development or progression of cancers, through the preparation and use of antisense constructs which incorporated the regions that are complementary to distinct intron regions of the gene to be down-regulated. It is believed that the present invention will be generally applicable to the down-regulation of any gene which comprises a distinct intron region. However, it is proposed that the invention will find particular application in the down-regulation of oncogene expression, particularly those oncogenes that are activated through mutation of coding sequences, and even more particularly, to those oncogenes which are members of family wherein one desires to leave unaltered the expression of other family members.

25

For this and other reasons, the present invention will have particular application to the selective inhibition of ras gene expression. For example, in the case of ras gene tumorigenesis, only one of the various ras gene family members undergoes mutation-based protooncogene activation. The remaining, non-activated ras gene family member(s) serve useful cellular biological functions and are apparently required for normal cellular function. Thus, it is desirable to specifically down-regulate the activated ras gene product, while leaving essentially unaffected, the non-

30
35

-16-

activated *ras* gene counterparts. Thus, the present invention will have a particular application in the context of preferentially controlling *ras* gene expressing.

5

While the present invention is exemplified in terms of the control of *ras* gene expression, there is, of course, no reason why the present invention will not be similarly applicable to other genes and gene families, in
10 light of the disclosure herein and the general knowledge and skill in the art.

Generally speaking, to practice the present invention in the context of the *ras* gene system it will
15 be first important to determine which of the various *ras* genes is involved in the oncogenic process to be retarded. This is a fairly straightforward undertaking, and involves generally that one first obtain cells which are expressing the activated *ras* gene product. To
20 determine the nature of the activation, one then simply extracts DNA, amplifies the specific sequences of interest (see Table I below), and shows the presence or absence of the mutation by specific hybridization with a known oligonucleotide sequence.

25

After the particular activated *ras* gene has been identified, an appropriate intron region is then selected for constructing the antisense construct. The most appropriate introns are those which have little or no
30 homology to other known genes. In general, it will be preferable to identify an appropriate intron structure for use in connection with the present invention an analysis of the nucleic sequence of the intron, and comparison with selected that of introns of other family
35 members or related genes. The best choice of introns will be those having 1) a different length from

-17-

corresponding introns and similar location in other members of the gene family, and 2) little or no sequence homology with the introns of the other members.

5 An alternative, and sometimes simpler method to identify distinct introns involves a comparison of sequence homologies can be ascertained by cross-hybridization of introns from one family member with those of other genes.

10

 In any event, representative methods for cloning *ras* genes corresponding to the N-*ras*, K-*ras* and H-*ras* genes, have been described in the literature (McGrath, et al., 1983; Shimizu, et al., 1983; Yamamoto, et al., 1985; 15 Kraus, et al., 1984). These teachings should provide those of skill in the art with adequate direction where one seeks to obtain sequences corresponding to the various *ras* gene intron.

20

 A preferred method for cloning intron sequences is through the application of PCR-amplified cloning. In this relatively well known technique, one employs oligonucleotide primers which allow the specific amplification of the desired intron region. The primer 25 itself corresponds to exon sequences, in that these sequences will most likely be generally available in the scientific literature for the particular application envisioned. Of course, where the intron sequences are known, computer assisted comparisons may be carried out 30 to identify distinct regions, and appropriate PCR primers designed accordingly.

 Recombinant clones which incorporate intron DNA are readily achieved through the PCR amplification of the 35 distinct desired region using primers, e.g., that border the region, incorporating the amplified DNA into a

-18-

recombinant clone, and selecting recombinant clones which have received the intron DNA-bearing clones. The intron DNA containing clones are then purified, and, preferably, the cloned DNA sequenced sufficiently to ensure that it
5 contains the desired sequences.

Intron DNA is then removed from the vector employed for intron DNA cloning, and employed in the construction of appropriate antisense vectors. This will entail, of
10 course, placing the intron DNA in an antisense direction behind an appropriate promoter and positioned so as to bring the expression of the antisense intron under control of the promoter.

When selecting primers for intron sequence
15 amplification, one will typically desire to employ primers such that at least 50 and preferably 100-200, nucleotides of the intron are amplified and thereby cloned. In general, it is believed that the larger the
20 distinct antisense intron region is, the better able it will be to selectively down-regulate the targeted gene. Furthermore, it is believed that particular advantages will be realized through the selection of intron regions which include intron/exon boundaries, or simply just the
25 intron side of the intron/exon boundaries. The reason for this is that RNA processing takes place at the intron/exon boundary of the RNA and it is believed that the antisense intron DNA will have its greatest effect when targeted to this junction.

30 The particular vector which ones employs for introduction of antisense intron coding sequences is not believed to be particularly crucial to the practice of the present invention, so long as the vector is capable
35 of introducing the nucleic acid coding sequences into the genome of the targeted cell in a relatively stable

-19-

fashion. By way of illustration, but not limitation, one can mention the following vectors, including N2A, LN, LNSX, Adenovirus and Adeno-associated virus.

5 The most preferred vector construct for targeting cells is the LNSX retroviral vector. This vector is based on the N2 vector, which contains the extended packaging signal that allows for the production of the vector at a high titer. This vector was modified by
10 inserting a stop codon in place of the Pr65 gag start codon to prevent synthesis of Pr 65 gag, and by replacing the upstream region of the vector with the homologous region from Moloney murine sarcoma virus. These alterations prevent synthesis of viral proteins from the
15 vector. Splicing is not required for efficient neo-protein expression. The neo gene is expressed from the upstream LTR promoter. An SV promoter and downstream cloning sites were added so that inserted genes such as the K-ras segment can be expressed from the internal
20 promoter.

 The following examples are included to provide actual working protocols which the inventors have developed or adopted for carrying out preferred
25 embodiments of the invention. Those of skill in the art will readily appreciate that many of the techniques employed in the following examples are illustrative of standard laboratory practices, which have been found by the inventors to work well in the practice of the
30 invention. It will, however, be apparent to those of skill in the art, in light of the following examples, that numerous materials and/or modifications and procedures and nevertheless achieve a useful result.

-20-

EXAMPLE I**SPECIFIC INHIBITION OF K-RAS EXPRESSION
AND TUMORIGENICITY OF LUNG CANCER CELLS BY ANTISENSE RNA**

5

A. INTRODUCTION

A wide spectrum of human cancers harbor *ras* genes activated by a single point mutation (Barbacid, 1987; Rodenhuis, et al., 1987; Bos, 1989; Rodenhuis, et al., 1990; Mabry, et al., 1988; Santos, et al., 1984; Taya, et al., 1984; Cline, et al., 1987; Feig, et al., 1984; Vogelstein, et al., 1988; Kumar, et al., 1990). Despite considerable knowledge of the structural aspects of the *ras* gene product, the functional role in physiological and pathological processes remains elusive (Barbacid, 1987). Cellular location and structural and biochemical similarities to G proteins suggest that *ras* gene products are involved in signal transduction (Bos, et al., 1987; Hurley, et al., 1984). The present example describes the preparation and use of an antisense RNA construct to block selectively the production of the mutated protein in the human non-small cell lung cancer (NSCLC) cell line NCI-H460A. The direct contribution of the mutated p21 protein to the malignant phenotype was also examined.

25

B. MATERIALS AND METHODS

H460, H322, H226, H522 non-small cell lung cancer (NSCLC) cell lines were generously provided by Drs. J.D. Minna, A.F. Gazdar, NCI Naval Medical Oncology Branch, Bethesda, Maryland. All cell lines were grown in regular RPMI medium, 5% FCS, in routine culture.

30

-21-

1. Plasmid Construction

5 A 2-kb genomic DNA fragment from the K-ras proto-oncogene was subcloned into an Apr-1-neo vector in both sense and antisense orientation. A 2-kb Eco RI/Pst I
10 fragment containing second and third exon sequences together with adjoining flanking intron sequences was isolated from the SP6 vector (Oncogene Sciences) and Klenow enzyme was used to make blunt ends. Apr-1-neo
15 vector was digested with Bam HI and blunt end ligation was performed to obtain the Apr-1-neo AS or Apr-1-neo A constructs.

2. DNA Transfections

15 H460a or H322a cells were electroporated with 10 ug of Apr-1-neo AS or Apr-1-neo S plasmid DNA. Forty-eight hours after transfection G418 was added into the medium at a concentration of 300 $\mu\text{g/ml}$ for H460a and 200 $\mu\text{g/ml}$
20 for H322a. Individual colonies were picked up and grown in culture for further analysis.

3. Southern blot analysis

25 High molecular weight DNA was isolated and digested with Eco RI (Boehringer-Mannheim) (20 μg), and electrophoresed in 0.8% agarose gel, transferred onto a Gene Screen membrane (NEN) and hybridized with a P^{32} nick
30 translated 2kb genomic K-ras DNA probe.

4. Measurement of RNA Expression

35 Total cellular RNA was isolated from the cell lines (Chomczynsky, et al., 1987). Twenty microgram of total RNA was size fractionated in MOPS/formaldehyde gel, transferred onto a Gene Screen membrane and processed for

-22-

hybridization with riboprobes. A 302 bp genomic DNA of the K-ras gene was amplified by PCR spanning the third exon and intron sequences and was subcloned into a bluescript vector. In vitro S and AS RNA probes were
5 synthesized using either a T7 or T3 promotor.

5. Polymerase Chain Reaction

Polymerase chain reactions were performed as
10 previously described using Taq 1 DNA polymerase (Saiki, et al., 1985). Oligonucleotide primers corresponding to region the 5' and 3' regions of codons 12 and 61 of human K-ras, H-ras, and N-ras genes were synthesized. Two
15 micrograms of genomic DNA was subjected to 35 cycles of amplification. DNA sequences of oligonucleotide primers used for PCR amplification are listed below in Table 1.

-23-

6. Slot Blot Oligonucleotide Hybridization

- 25 PCR amplified DNA samples (12.5, 25, 50 ng) were blotted onto a Gene Screen membrane using a slot blot apparatus (Schleicher & Schuell). The filters were prehybridized and hybridized at 55°C in 6X SSC, 5X Denhardt's and 100 µg/ml of salmon sperm DNA for 2 h.
- 30 Filters were washed twice in 6X SSPE at room temperature and once for 30 mins at 58°C. Finally, blots were washed for 5 mins at 64°C. The filters were exposed to x-ray film for 12 - 24 h at -80°C.

35 7. Direct Sequencing of PCR Amplified DNAs

-24-

PCR DNA corresponding to the second exon was purified in 8% polyacrylamide gel. A single DNA band was excised and purified DNA was used for asymmetric amplification in 100 μ l of PCR reaction mixture. One (KA 61) amplimer was added to this mixture. After 20 cycles, single-stranded DNA was purified through gene clean (Bio 101) and DNA was eluted in 15 μ l of water. Four microliters of DNA were mixed with 4 μ l of 10x Taq 1 buffer and 1 μ l (10 pmol) of a second amplimer (KB 61) was used as a sequencing primer and DNA was sequenced using a Sequenase kit.

8. RNA PCR Analysis

cDNA synthesis was carried out in a total volume of 20 μ l containing 5 μ g of total RNA and oligo (dT) as a primer (Becker-Andre, et al., 1989). A portion of the cDNA corresponding to the first and second exons was amplified to monitor the level of endogenous K-ras mRNA (Fig. 2A) using KA12 and KB61 amplimers. Denaturation, annealing, and extension were done at 92°C for 1 min, 51°C for 1 min and 74°C for 1 min, respectively. However, annealing temperatures for N-ras and H-ras were 44°C and 42°C, respectively. In addition, two amplimers were also used in the same reaction mixture to amplify a 118-bp fragment of the p53 gene as an internal control. PCR products were either transferred onto a membrane and hybridized with ³²P labelled cDNA probe or alternatively, there were directly labelled during the last cycle of amplification by adding 1 uCi of ³²P dCTP. The labelled PCR products were loaded on an 8% nondenaturing polyacrylamide gel. The gel was photographed after ethidium bromide staining, dried, and exposed to x-ray film overnight at -80°C.

-25-

9. Western blot analysis of RAS protein

Protein extracts were prepared by lysing cell in TBS (10 mM TRIS ph 7.5, 100 mM NaCl, 1 mM PMSF 1% NP40, 1% deoxycholate. The extracts were cleaned by centrifugation at 10,000Xg for 1 h. The protein concentration of the supernatant was calculated spectrophotometrically. Five hundred micrograms of protein were size fractionated in 12.55% SDS polyacrylamide gel and electroblotted onto nitrocellulose membranes. Ras specific p21 protein was detected using either K-ras or pan ras specific monoclonal antibody (Oncogene Sciences) followed by ^{125}I -labelled goat anti-mouse second antibody.

10. Tumorigenicity in Nude Mice

The tumorigenicity of these cell lines was examined by subcutaneous inoculation of 10^5 (Fig. 3B) and 10^6 cells in nu/nu mice. Each cell line was injected into 5 animals. Tumors were measured with linear calipers in 2 orthogonal directions by the same observer.

C. RESULTS AND DISCUSSION

Segments of the K-ras gene containing first and second exons were amplified from a number of NSCLC cell line DNAs by polymerase chain reaction (Saiki, et al, 1985) and subsequently hybridized with a set of ^{32}p -labelled oligonucleotide probes (Fig. 1A-1 & 2). Mutations were confirmed by a direct PCR DNA sequencing method. A homozygous mutation at codon 61 was detected in the NCI-H460A large cell undifferentiated NSCLC cell line with a normal glutamine residue (CAA) substituted by histidine (CAT). This cell line is highly tumorigenic in nude mice.

-26-

A recombinant plasmid clone was constructed using a wild-type 2 kb K-ras genomic DNA segment carrying second and third exons together with flanking intron sequences subcloned into an Apr-1-neo expression vector (Gunning, et al., 1984) in the antisense orientation (AS; Fig. 1G). Sense orientation (S) plasmid constructs were used as a control (Fig. 1B). AS or S K-ras RNA synthesis was accomplished by transfecting H460a cells, a cloned derivative of the NCI-H460A cell line, with Apr-1-neo AS or Apr-1-neo S constructs by electroporation. The β -actin promoter of the vector was constitutively capable of directing the synthesis of RNA from the inserted DNA. The Apr-1-neo vector offered suitable G418 marker gene expression for selection of the transfectants.

15

Individual G418 resistant colonies were selected and grown in culture for further analysis. Stable integration of the plasmid DNA in the transfectants was examined by Southern hybridization with a 2 kb DNA insert from the original plasmid clone as a probe (Fig. 1C). The southern blot analysis showed a single 3 kb Eco RI band corresponding to the endogenous K-ras gene in the parental H460a cell line, but additional bands were observed in the individual clones indicating single or multiple copy inserts.

25

The extent of stable AS RNA expression and its effect on the endogenous K-ras mRNA level was investigated. Total RNA was extracted from subconfluent, growing cultures (Gunning, et al., 1987). The presence of AS and S RNA was detected by northern blot hybridization using either an S or AS RNA probe synthesized in vitro from a Bluescript vector carrying a 302 bp K-ras DNA insert corresponding to the third exon and part of the intron sequences (Fig. 1D). Interestingly, the clones carrying the Apr-1-neo AS

30

35

-27-

vector show one RNA band at about 1.5kb, but the cells carrying the S construct show two RNA species. The reason for this is unknown, but the possibility exists that the RNA synthesized from the genomic DNA under control of the β -actin promoter could be processed in vivo. However, no corresponding hybridization band was detected in H460a cells, which indicated a significantly higher level of K-ras RNA was synthesized under the β -actin promoter.

Next, the p21 protein level in these transfectants was analyzed by western blot analysis (Fig. 1E, F). A K-ras- specific p21 monoclonal antibody (Oncogene Science) was used to determine the level of K-ras protein in transfectants, parental H460a cells, and Calu-1 cells, which have a high level of K-ras gene expression (Fig. 1E). Western blot analysis showed a 95% reduction in K-ras p21 protein synthesis in the clones expressing the AS RNA, while parental cells, S K-ras clones, and Calu-1 cells showed a significant level of K-ras p21 protein. These results indicate that AS RNA can effectively block the synthesis of K-ras specific protein. Since members of the ras gene family share a great deal of sequence homology and code for a similar p21 ras protein, we examined the total ras protein product in these clones was examined using a PAN ras monoclonal antibody (New England Nuclear) to determine whether a reduced level of K-ras protein reflects any change in H-ras and N-ras p21 protein synthesis (Fig 1F). Western blot analysis revealed only a slight decrease in overall ras protein level in all clones containing Apr-1-neo-AS, as compared to 460a parental cells.

The effect of AS RNA on the specific production of mature endogenous K-ras mRNA was analyzed by cDNA PCR (Fig. 2). cDNA synthesized from the total RNA

-28-

(Chomczynsky, et al., 1987) was subjected to PCR amplification using amplimers corresponding to the 5'-end of the first exon and the 3'-end of the second exon (Fig. 2A). Because the AS RNA was generated only from a second and third exon of the K-ras gene, PCR amplified cDNA represented the level of endogenous K-ras mRNA. A 246-bp amplified DNA fragment was labelled by ³²P dCTP and subsequently analyzed by polyacrylamide gel electrophoresis. In addition, a 118-bp segment of endogenous p53 cDNA was co-amplified in the same reaction mixture using p53 specific amplimers to serve as an internal control for the PCR.

Results showed that H460a cells, clones expressing S RNA, and the Calu-1 cell line expressed K-ras mRNA, as evidenced by the presence of a high level of amplification of the 246-bp cDNA product (Fig. 2B). H460a clones expressing AS RNA showed very little amplification, and cellular K-ras mRNA synthesis appeared to be completely inhibited (Fig. 2B, lanes 5 and 6). In contrast, the endogenous p53 expression remained unaffected. This prompted us to investigate the level of expression for other ras genes in these clones. We employed the same cDNA PCR methodology to analyze the N-ras and H-ras mRNA level using N-ras and H-ras-specific oligonucleotides as amplimers. A steady state level of H-ras and N-ras gene expression was observed, but no obvious change either in Apr-1-neo AS or Apr-1-neo S transfectants was noticed (Fig. 2C, D). The p53 gene expression serving as a control in these experiments remained unaffected. Thus, inhibition of K-ras expression by our AS RNA construct is specific.

H460a clones expressing AS K-ras RNA continued to grow in culture. However, H460a Apr-1-neo AS transfectants showed a three-fold reduction in growth,

-29-

compared to the H460a Apr-1-neo-S transfectants and the parental H460a cells (Fig. 3A). The H322 NSCLC cell lung cancer cell line has wild-type ras family genes. H322 Apr-1-neo AS and Apr-1-neo S transfectants had identical growth characteristics, indicating that inhibition of wild-type K-ras is not sufficient to alter tumor cell growth rate. These results together indicate that the presence of sense K-ras RNA did not alter the growth kinetics of H460a cells. However, the marked growth retardation of the K-ras Apr-1-neo-AS transfectants suggests that the mutated p21 protein contributes to the faster growth rate of these cells.

The tumorigenicity of cell lines expressing AS RNA was assessed by subcutaneous injection of 10^5 and 10^6 cells in nu/nu mice. Subcutaneous inoculation of H460a cells at both doses led to the formation of tumors in 15 days in all mice (3 to 5 mice per group in 3 separate experiments). No tumor developed in mice injected with 10^5 cells for both clones of H460a AS cells during 120 days of observation in a total of ten mice, whereas all mice receiving H460a cells developed tumors. When the inoculum was increased to 10^6 cells, tumors grew in all mice, but the tumors in mice receiving AS clones grew at a slower rate than H460a cells or the S control (Fig. 3B). Tumors were excised and analyzed for K-ras expression by cDNA-PCR. K-ras expression was not detected in tumors arising from injection of AS clones but was present in S clones and H460a tumors.

30

The above experiments indicate that in H460a cells engineered to synthesize AS K-ras RNA, the level of K-ras mRNA and K-ras p21 protein are effectively down regulated. Reduction in the expression of K-ras mutated gene reproducibly reduced the rate of tumor growth in nu/nu mice. Our studies show that a construct can be

35

-30-

made that distinguishes among members of the ras family. Previous studies with AS oligonucleotides showed inhibition of p21 expression which led to cell death (Brown, et al., 1989; Debus, et al., 1990). Our data
5 indicate that AS RNA generated from the genomic DNA of the K-ras gene can specifically inhibit K-ras expression. In our model inhibition of activated K-ras reduced the growth rate of the H460a cells. However, there was no effect on cell viability or continued growth in culture.
10 This suggests that redundancy in p21 expression may compensate for absence of expression by one member of this family so that functions essential for maintenance of cell viability are preserved. However, tumorigenicity was maintained in the absence of activated K-ras
15 expression although the rate of tumor growth was diminished. We hypothesize that in human NSCLC, ras mutations confer a growth advantage to the malignant cell.

CLAIMS:

1. An antisense RNA molecule capable of selectively
5 inhibiting the expression of a gene product of a selected gene, the antisense RNA molecule including a region that is complementary to and capable of hybridizing with an intron region of the selected gene.
- 10 2. The antisense RNA molecule of claim 1, wherein the selected gene is a member of a gene family and encodes an intron region that is distinct from intron regions of another family member, the antisense RNA molecule being
15 capable of selectively inhibiting the expression of the selected gene product over that of another member of the family.
- 20 3. The antisense RNA molecule of claim 1, wherein the RNA molecule comprises a sequence that is complementary to an entire intron.
- 25 4. The antisense RNA molecule of claim 1, wherein the RNA molecule comprises a sequence that is complementary to exon region sequences of the selected gene.
- 30 5. The antisense RNA molecule of claim 4, wherein sequences complementary to the intron and exon regions of the selected gene are adjacent, and includes a sequence that is complementary to an intron/exon junction of the
35 selected gene.

-36-

6. The antisense RNA molecule of claim 2, wherein the selected gene is an oncogene, and the RNA molecule inhibits the expression of the oncogene.

5

7. The antisense RNA molecule of claim 6, wherein the gene family comprises the *ras*, *myc*, *erb* or *jun* family of oncogenes.

10

8. The antisense RNA molecule of claim 6, wherein the oncogene is one which is activated by a point mutation.

15

9. The antisense RNA molecule of claim 8, wherein the oncogene is a *ras* oncogene.

10. The antisense RNA molecule of claim 9, wherein the RNA encodes a sequence that is complementary to an intron region of the p21 K-*ras* oncogene that is not found in an intron of H-*ras* or N-*ras*.

25 11. The antisense RNA molecule of claim 10, wherein the intron region comprises a region from intron II of the p21 K-*ras* oncogene.

30 12. The antisense RNA molecule of claim 11, wherein the molecule encodes sequences complementary to exons II and III and intron II of K-*ras*.

-37-

13. A DNA molecule capable of expressing an antisense RNA molecule in accordance with any one of claims 1 through 12.

5

14. A nucleic acid molecule comprising a coding region that is capable of expressing an antisense RNA molecule for selectively inhibiting the expression of a product of a selected gene, the DNA coding region encoding an
10 antisense RNA that includes a region that is complementary to and capable of hybridizing with an intron region of the selected gene.

15 15. The nucleic acid molecule of claim 14, wherein the selected gene is a member of a gene family and encodes an intron region that is distinct from intron regions of another family member, the nucleic acid molecule encoding an antisense RNA molecule that is capable of selectively
20 inhibiting the expression of the selected gene product over that of another member of the family.

16. The nucleic acid molecule of claim 14,, further
25 defined as a DNA molecule.

17. The nucleic acid molecule of claim 16, wherein the DNA molecule encodes an RNA molecule which has a sequence
30 that is complementary to an entire intron which includes the distinct intron region.

18. The nucleic acid molecule of claim 16, wherein the
35 DNA molecule encodes RNA sequences which are complementary to intron and exon regions of the selected

-38-

gene, and includes a sequence that is complementary to an intron/exon junction of the selected gene.

- 5 19. The nucleic acid molecule of claim 16, wherein the DNA molecule encodes an antisense RNA that is complementary to a selected oncogene member of a family of genes, and the RNA molecule inhibits the expression of the oncogene.

10

20. The nucleic acid molecule of claim 19, wherein the gene family comprises the *ras*, *myc*, *erb* or *jun* family of oncogenes.

15

21. The nucleic acid molecule of claim 19, wherein the oncogene is one which is activated by a point mutation.

20

22. The nucleic acid molecule of claim 21, wherein the oncogene is a *ras* oncogene.

- 25 23. The nucleic acid molecule of claim 22, wherein the DNA molecule encodes an RNA that comprises a region that is complementary to an intron region of the p21 K-*ras* oncogene, wherein the intron region is not found in an intron of H-*ras* or N-*ras*.

30

24. The nucleic acid molecule of claim 23, wherein the DNA molecule encodes an RNA that comprises a region that is complementary to a region from intron II of the p21 K-*ras* oncogene.

35

-39-

25. The nucleic acid molecule of claim 24, wherein the DNA molecule encodes sequences complementary to exons II and III and intron II of K-ras.

5

26. The nucleic acid molecule of claim 14, wherein the coding region is positioned adjacent to and under the control of a promoter that is capable of being expressed in a human cell.

10

27. The nucleic acid molecule of claim 26, wherein the promoter comprises a human cellular or viral promoter.

15

28. The nucleic acid molecule of claim 27, wherein the promoter comprises an RSV, N2A, LN, LNSX, LNSN, SV40, LNCX or a β -actin promoter.

20

29. The nucleic acid molecule of claim 28, wherein the promoter comprises the β -actin promoter.

25

30. The nucleic acid molecule of claim 14, further defined as a vector.

30

31. The nucleic acid molecule of claim 30, further defined as a plasmid.

35

32. The nucleic acid molecule of claim 30, further defined as a retrovirus.

-40-

33. A method for selectively inhibiting the expression of a gene product of a selected gene in a cell, the method comprising

5 preparing an antisense RNA molecule that includes a region that is complementary to and capable of hybridizing with an intron region of the selected gene; and

10 introducing the antisense RNA into the cell in an amount effective to inhibit the expression of the gene product.

15 34. The method of claim 32, wherein the antisense RNA is introduced into the cell by introduction of a DNA molecule that encodes and is capable of expressing the antisense RNA molecule.

20 35. The method of claim 33, wherein the DNA molecule is introduced into the cell by means of a retrovirus.

25 36. The method of claim 33 or 34, wherein the DNA molecule comprises the DNA molecule of claim 14.

30 37. The method of claim 32, wherein the selected gene comprises an oncogene.

35 38. The method of claim 36, wherein the selected gene comprises a selected oncogene member of a family of genes.

-41-

39. A method for the inhibition of tumorigenicity of *ras*-transformed cancer cells comprising:

5 preparing a vector capable of expressing an
 antisense RNA molecule which comprises an intro
 region of the p21 K-*ras* oncogene that is not
 found in an intron of H-*ras* or N-*ras*;

10 introducing the vector into the lung cancer cells
 under conditions allowing the expression of the
 antisense RNA in amounts effective to inhibit
 the tumorigenicity of the lung cancer cells.

15 40. A method for selectively inhibiting a selected *ras*
 gene in a cell over other *ras* genes of the cell, the
 method comprising:

20 testing the cell to identify the selected *ras* gene;

 preparing an antisense RNA molecule that includes a
 region that is complementary to and capable of
 hybridizing with an intron region of the
 selected gene; and

25 introducing the antisense RNA into the cell in
 amounts effective to selectively inhibiting the
 selected *ras* gene.

30 41. A method for selectively inhibiting the expression
 of a gene product of a selected gene in a cell, the
 method comprising:

35 preparing an antisense RNA molecule that includes a
 region that is complementary to and capable of

-42-

hybridizing with an intron region of the
selected gene; and

5 introducing the antisense RNA into the cell in an
 amount effective to inhibit the expression of
 the gene product.

10 42. The method of claim 32, wherein the antisense RNA is
 introduced into the cell by introduction of a DNA
 molecule that encodes and is capable of expressing the
 antisense RNA molecule.

15 43. The method of claim 41, wherein the DNA molecule is
 introduced into the cell by means of a retrovirus.

20 44. The method of 41 or 42 wherein the DNA molecule of
 claim 14.

25 45. The method of claim 40, wherein the selected gene
 comprises an oncogene.

30 46. The method of claim 44, wherein the selected gene
 comprises a selected oncogene member of a family of
 genes.

35 47. A method for selectively inhibiting a selected ras
 gene in a cell over other ras genes of the cell, the
 method comprising:

-43-

testing the cell to determine the identity of the
ras gene to be inhibited;

5 preparing an antisense RNA molecule which comprises
a sequence that is complementary to a distinct
intron region of the identified ras gene, and
is capable of hybridizing to such a region;

10 introducing the antisense RNA into the cell in
amounts effective to selectively inhibiting the
selected ras gene.

15 48. The method of claim 47, wherein the identified ras
gene is a ras oncogene.

20 49. The method of claim 48, wherein the identified ras
gene is a K-ras, H-ras or N-ras oncogene.

50. The method of claim 49, wherein the identified ras
gene is a K-ras oncogene.

25 51. The method of claim 47, wherein the antisense RNA is
introduced into the cell by a method comprising the steps
of:

30 preparing a recombinant vector which comprises a
nucleic acid sequence capable of expressing the
antisense RNA in the cell; and

35 introducing the vector into the cell in a manner
which allows the expression of the encoded

-44-

antisense RNA therein in at a level sufficient to inhibit said expression.

- 5 52. The method of claim 51, wherein the recombinant vector is capable of stably integrating into the cell.

⁹ Special categories of cited documents:

- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

"d" document member of the same patent family

**ANNEX TO THE INTERNATIONAL SEARCH REPORT
ON INTERNATIONAL PATENT APPLICATION NO.**

US 9201852

SA 58494

This annex lists the patent family members relating to the patent documents cited in the above-mentioned international search report.
The members are as contained in the European Patent Office EDP file on 04/08/92
The European Patent Office is in no way liable for these particulars which are merely given for the purpose of information.
